

What a passing check proves. And what it doesn't.

For the bank reviewer opening a pack from someone they don't have to trust.

No upload. No account.

```
npx @halvorai/ingest
verify-pack ./pack.zip
```

It prints a pass or fail for each check and exits non-zero if anything fails.

Manifest

signed with our public pack key

Files

each SHA-256 against the manifest

Events

each one against the source's signature

Hash chain

links recomputed, daily anchors checked

- The pack is exactly what we signed.
- The events are exactly what the customer's source signed.
- No event in the covered range was removed.

It does not mean every payment is legitimate.

The pack supports the bank's own investigation. It doesn't replace it, and we never file on anyone's behalf.

Banks: what would you check first?

A reviewer needs no account. A share link opens one pack, expires within 30 days, can be revoked, and every view is logged.
